

Hi !

Thanks a lot for taking the time to chat for the **Data Engineering Manager** role at Félix! I am happy to move forward with your process.

The next step is a take-home assignment. You can find the details below. You'll also find another doc [HERE](#).

Ideally, you should submit your solution within 4-5 business days, but let me know if you need more time.

Question 1

You work as a data-engineer for a fintech focused on remittances.

We provide you with 3 csv files as data source from backend systems. They are payments.csv, receipts.csv, disbursements.csv

A remittance is composed of a payment made from the customer sending money, and a disbursement of the money to the person receiving it. Payments and disbursements are linked by receipts.

Using these 3 csv files as data sources, please:

- Create a DBT project connecting to any database of your preference which will work as data warehouse
- Ingest the 3 data sources as raw data on your database. Use a raw schema / dataset for that. DON'T USE SEEDS FOR SOURCES.
- Create a first layer of data ingesting the source, deduplicating it and applying schema patterns
- Create any necessary intermediate layer to join common data by business context
- Think about your data modelling
- Generate the following metrics. Create how many marts you think are required. Be creative if you don't have a clear understanding of any of them.
 - Total amount transacted by month
 - Classify users that represent 50% of the total volume transacted
 - Recurring customers (create your definition)
 - Classify providers by failed disbursements
 - Clusters of users sending to same beneficiaries

- Chargeback rate
- Add data tests to your models
- Send you project to a github repo and share it with us
